1.(10%) A Carnot heat pump is used to heat and maintain a residential building at 24°C . An energy analysis of the house reveals that it loses heat at a rate of 4500 kJ/h per $^\circ\text{C}$ temperature difference between the indoors and the outdoors. For an outdoor temperature of 2°C , determine (a) the coefficient of performance and (b) the required power input to the heat pump.

2.(15%) A computer cooled by a fan contains eight PCBs, each dissipating 10 W power. The height of the PCBs is 12 cm and the height is 18 cm . The cooling air is supplied by a 25-W fan mounted at the inlet. If the temperature rise of air as it flows through the case of the computer is not to exceed 10°C , determine (a)(10%) the flow rate of the air that the fan needs to deliver and (b)(5%) the fraction of the temperature rise of air that is due to the heat generated by the fan and its motor. (note: air $c_p = 1.005 \text{ kJ/kg}\cdot^\circ\text{C}$ at room temperature)

3. (15%) Chips of width $L = 15 \text{ mm}$ on a side are mounted to a substrate that is installed in an enclosure whose walls and air are maintained at a temperature of $T_{\text{air}} = 25^\circ\text{C}$. The chips have an emissivity of $\epsilon = 0.60$ and a maximum allowable temperature of $T_s = 85^\circ\text{C}$. (note: Boltzmann constant $\sigma = 5.67 \cdot 10^{-8} \text{ W/m}^2\cdot\text{K}^4$)

- (a) (10%) If heat is rejected from the chips by radiation and natural convection, what is the maximum operating power of each chip? The convection coefficient depends on the chip-to-air temperature difference and may be approximated as $h = C(T_s - T_\infty)^{1/4}$, where $C = 4.2 \text{ W/m}^2\cdot\text{K}^{3/4}$.
- (b) (5%) If a fan is used to maintain airflow through the enclosure and heat transfer is by forced convection, with $h = 250 \text{ W/m}^2\cdot\text{K}$, what is the maximum operating power?

4. (20%) A composite cylindrical wall is composed of two materials of thermal conductivity k_A and k_B , which are separated by a very thin, electric resistance heater for which interfacial contact resistances are negligible. Liquid pumped through the tube is at a temperature $T_{\infty,i}$ and provides a convection coefficient h_i at the inner surface of the composite. The outer surface is exposed to ambient air, which is at $T_{\infty,o}$ and provides a convection coefficient of h_o . Under steady-state conditions, a uniform heat flux of q_h'' is dissipated by the heater.

- (6%) Sketch the equivalent thermal circuit of the system and express all resistances in terms of relevant variables.
- (6%) Obtain an expression that may be used to determine the heater temperature, T_h .
- (8%) Obtain an expression for the ratio of heat flows to the outer and inner fluids, q_o'/q_i' . How might the variables of the problem be adjusted to minimize this ratio?

5. (20%) A house has a composite wall of wood, fiberglass insulation, and plaster board, as indicated in the sketch. On a cold winter day, the convection heat transfer coefficients are $h_o = 60 \text{ W/m}^2 \cdot \text{K}$ and $h_i = 30 \text{ W/m}^2 \cdot \text{K}$. The total wall surface area is 350 m^2 . (note: $k_p = 0.17 \text{ W/m} \cdot \text{K}$, $k_b = 0.038 \text{ W/m} \cdot \text{K}$, $k_s = 0.12 \text{ W/m} \cdot \text{K}$.)

- (5%) Determine a symbolic expression for the total thermal resistance of the wall, including inside and outside convection effects for the prescribed conditions.
- (9%) Determine the total rate of heat loss through the wall.
- (3%) If the wind were blowing violently, raising h_o to $300 \text{ W/m}^2 \cdot \text{K}$, determine the percentage increase in the rate of heat loss.
- (3%) What is the controlling resistance that determines the amount of heat flow through the wall?

6. (20%) The heat transfer coefficient for air flowing over a sphere is to be determined by observing the temperature-time history of a sphere fabricated from pure copper. The sphere, which is 12.7 mm in diameter, is at 66°C before it is inserted into an airstream having a temperature of 27°C . A thermocouple on the outer surface of the sphere indicates 55°C 69 s after the sphere is inserted into the airstream. Assume and then justify that the sphere behaves as a spacewise isothermal object and calculate the heat transfer coefficient. (note: pure copper at 60°C , $\rho = 8933 \text{ kg/m}^3$, $c_p = 389 \text{ J/kg} \cdot \text{K}$, $k = 398 \text{ W/m} \cdot \text{K}$)
